This Installation, Operation, and Maintenance Manual is designed to help you achieve the best performance and longest life from your Gorman-Rupp pump.

This pump is an 80 Series, semi-open impeller, self-priming centrifugal model. The pump is designed for straight-in suction where the medium being pumped enters directly into the impeller eye. It will handle most non-flammable, non-volatile liquids that may be mildly abrasive. The basic material of construction for wetted parts is gray iron, with a steel impeller shaft.

If there are any questions regarding the pump or its application which are not covered in this manual or in other literature accompanying this unit, please contact your Gorman-Rupp distributor, or write:

The Gorman-Rupp Company P.O. Box 1217 Mansfield, Ohio 44901-1217

Gorm 70 E

Gorman-Rupp of Canada Limited 70 Burwell Road St. Thomas, Ontario N5P 3R7

For information or technical assistance on the power source, contact the power source manufacturer's local dealer or representative.

The following are used to alert maintenance personnel to procedures which require special attention, to those which could damage equipment, and to those which could be dangerous to personnel:

NOTE

Instructions to aid in installation, operation, and maintenance or which clarify a procedure.

CAUTION

Instructions which must be followed to avoid causing damage to the product or other equipment incidental to the installation. These instructions describe the requirements and the possible damage which could result from failure to follow the procedures.

Introduction

Page I-1

WARNINGS - SECTION A

THESE WARNINGS APPLY TO 80 SERIES BASIC PUMPS. GORMAN-RUPP HAS NO CONTROL OVER OR PARTICULAR KNOWLEDGE OF THE POWER SOURCE WHICH WILL BE USED. REFER TO THE MANUAL ACCOMPANYING THE POWER SOURCE BEFORE ATTEMPTING TO BEGIN OPERATION.

WARNING
-
// Before attempting to open or service the pump: //
// 1. Familiarize yourself with this manual. // // 2. Lock out or disconnect the power source to ensure // // that the pump will remain inoperative. // // 3. Allow the pump to cool if overheated. // // 4. Vent the pump slowly and cautiously. // // 5. Close the suction and discharge valves. // // 6. Check the temperature before opening any covers, // // plates, or plugs. //
// 7. Drain the pump. //
// ///////////////////////////////////
WARNING
// This pump is designed to handle most non-flammable, // // non-volatile liquids that may be mildly abrasive. Do // // not attempt to pump volatile, flammable or highly corro- // sive liquids which may damage the pump or endanger per- // sonnel as a result of pump failure. //
WARNING
// After the pump has been installed, make certain that the // // pump and all piping connects are tight, properly sup- // ported and secure before operation. //
WARNING
4,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,
// Do not operate the pump without shields and/or guards in // // place over the drive shafts, belts and/or couplings, or // // other rotating parts Exposed rotating parts can catch // // clothing, fingers, or tools, causing severe injury to // // personnel.

Section A.

WARNING
-
<pre>// Do not operate the pump against a closed discharge valve // // for long periods of time. This could bring the liquid // // to a boil, build pressure, and cause the pump to rupture // // or explode. //</pre>
WARNING
7/////////////////////////////////////
<pre>// Overheated pumps can cause severe burns and injury. If // // overheating of the pump occurs: //</pre>
// 1. Stop the pump immediately.
<pre>// 2. Allow the pump to cool. // // 3. Refer to instructions in this manual before re- // starting the pump. //</pre>
WARNING
// Do not remove plates, covers, gauges, pipe plugs, or // fittings from an overheated pump. Vapor pressure within // // the pump can cause parts being disengaged to be ejected // // with great force. Allow the pump to cool before servic- // ing. //
WARNING
// Never run this pump backwards. Be certain that rotation // is correct before fully engaging the pump. //

INSTALLATION - SECTION B

Since pump installations are seldom identical, this section offers only general recommendations and practices required to inspect, position, and arrange the pump and piping.

Most of the information pertains to a standard static lift application where the pump is positioned above the free level of liquid to be pumped.

If installed in a **flooded suction application** where the liquid is supplied to the pump under pressure, some of the information such as mounting, line configuration, and priming must be tailored to the specific application. Since the pressure supplied to the pump is critical to performance and safety, **be sure** to limit the incoming pressure to 50% of the maximum permissible operating pressure as shown on the pump performance curve.

For further assistance, contact your Gorman-Rupp distributor or the Gorman-Rupp Company.

Pump Dimensions

See Figure 1 for the approximate physical dimensions of this pump.

OUTLINE DRAWING

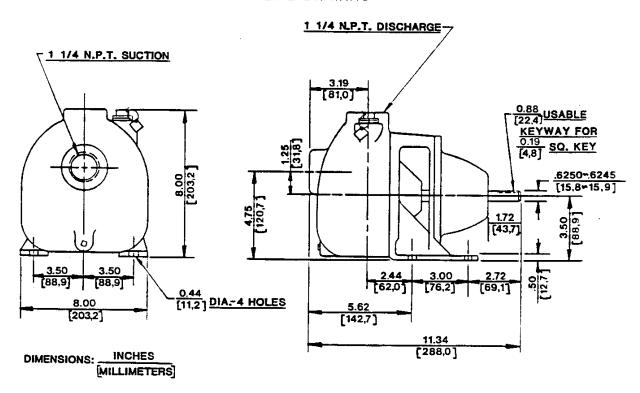

Figure 1. Pump Model 81 1/4A52-B

Section B.

PREINSTALLATION INSPECTION

The pump assembly was inspected and tested before shipment from the factory. Before installation, inspect the pump for damage which may have occurred during shipment. Check as follows:

- Inspect the pump for cracks, dents, damaged threads, and other obvious damage.
- b. Check for and tighten loose attaching hardware. Since gaskets tend to shrink after drying, check for loose hardware at mating surfaces.
- c. Carefully read all tags, decals, and markings on the pump assembly, and perform all duties indicated. Note the direction of rotation indicated on the pump. Check that the pump shaft rotates in the required direction.

CAUTION

Only operate this pump in the direction indicated by the arrow on the pump body and on the accompanying decal. Otherwise, the impeller could become loosened from the shaft and seriously damage the pump.

- d. Check all lubricant levels and lubricate as necessary. Refer to LUBRI-CATION in the MAINTENANCE AND REPAIR section of this manual and perform duties as instructed.
- e. If the pump and power source have been stored for more than 12 months, some of the components or lubricants may have exceeded their maximum shelf life. These must be inspected or replaced to ensure maximum pump service.

If the maximum shelf life has been exceeded, or if anything appears to be abnormal, contact your Gorman-Rupp distributor or the factory to determine the repair or updating policy. Do not put the pump into service until appropriate action has been taken.

POSITIONING PUMP

Lifting

Use lifting equipment with a capacity of at least 125 pounds. This pump weighs approximately 25 pounds, not including the weight of accessories and mounting base with power source. Customer installed equipment such as suction and discharge hoses must be removed before attempting to lift.

CAUTION

The pump assembly can be seriously damaged if the cables or chains used to lift and move the unit are improperly wrapped around the pump.

Mounting

Locate the pump in an accessible place as close as practical to the liquid being pumped. Level mounting is essential for proper operation. The pump may have to be supported or shimmed to provide for level operation or to eliminate vibration.

SUCTION AND DISCHARGE PIPING

Materials

Either pipe or hose may be used for suction and discharge lines; however, the materials must be compatible with the liquid being pumped. If hose is used in suction lines, it must be the rigid-wall, reinforced type to prevent collapse under suction. Using piping couplings in suction lines is not recommended.

Line Configuration

Keep suction and discharge lines as straight as possible to minimize friction losses. Make minimum use of elbows and fittings, which substantially increase friction loss. If elbows are necessary, use the long-radius type to minimize friction loss.

Connections to Pump

Before tightening a connecting flange, align it exactly with the pump port. Never pull a pipe line into place by tightening the flange bolts and/or couplings.

Lines near the pump must be independently supported to avoid strain on the pump which could cause excessive vibration, decreased bearing life, and increased shaft and seal wear. If hose-type lines are used, they should have adequate support to secure them when filled with liquid and under pressure.

Section B.

Gauges

Most pumps are drilled and tapped for installing discharge pressure and vacuum suction gauges. If these gauges are desired for pumps that are not tapped, drill and tap the suction and discharge lines not less than 18 inches from the suction and discharge ports and install the lines. Installation closer to the pump may result in erratic readings.

SUCTION LINES

To avoid air pockets which could affect pump priming, the suction line must be as short and direct as possible. When operation involves a suction lift, the line must always slope upward to the pump from the source of the liquid being pumped; if the line slopes down to the pump at any point along the suction run, air pockets will be created.

Fittings

Suction lines should be the same size as the pump inlet. If reducers are used in suction lines, they should be the eccentric type, and shouli be installed with the flat part of the reducers uppermost to avoid creating air pockets. Valves are not normally used in suction lines, but if a valve is used, install it with the stem horizontal to avoid air pockets.

Strainers

If a strainer is furnished with the pump, be certain to use it; any spherical solids which pass through a strainer furnished with the pump will also pass through the pump itself.

If a strainer is not furnished with the pump, but is installed by the pump user, make certain that the total area of the openings in the strainer is at least three or four times the cross section of the suction line, and that the openings will not permit passage of solids larger than the solids handling capability of the pump.

This pump is designed to handle up to 1/4 inch diameter spherical solids.

Sealing

Since even a slight leak will affect priming, head, and capacity, especially when operating with a high suction lift, all connections in the suction line should be sealed with pipe dope to ensure an airtight seal. Follow the sealant manufacturer's recommendations when selecting and applying the pipe dope. The pipe dope should be compatible with the liquid being pumped.

Suction Lines In Sumps

If a single suction line is installed in a sump, it should be positioned away from the wall of the sump at a distance equal to one and one-half times the diameter of the suction line.

If there is a liquid flow from an open pipe into the sump, the flow should be kept away from the suction inlet because the inflow will carry air down into the sump, and air entering the suction line will reduce pump efficiency.

If it is necessary to position inflow close to the suction inlet, install a baffle between the inflow and the suction inlet at a distance one and one-half times the diameter of the suction pipe. The baffle will allow entrained air to escape from the liquid before it is drawn into the suction inlet.

If two suction lines are installed in a single sump, the flow paths may interact, reducing the efficiency of one or both pumps. To avoid this, position the suction inlets so that they are separated by a distance equal to at least three times the diameter of the suction pipe.

Suction Line Positioning

The depth of submergence of the suction line is critical to efficient pump operation. Figure 2 shows recommended minimum submergence vs. velocity.

NOTE

The pipe submergence required may be reduced by installing a standard pipe increaser fitting at the end of the suction line. The larger opening size will reduce the inlet velocity. Calculate the required submergence using the following formula based on the increased opening size (area or diameter).

Section B.

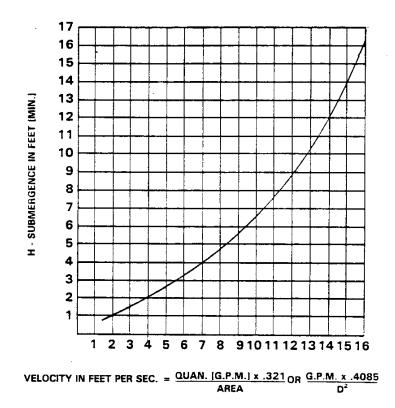

Figure 2. Recommended Minimum Suction Line Submergence Vs. Velocity

DISCHARGE LINES

Siphoning

Do not terminate the discharge line at a level lower than that of the liquid being pumped unless a siphon breaker is used in the line. Otherwise, a siphoning action causing damage to the pump could result.

Valves

A check valve in the discharge line is normally recommended, but it is not necessary in low discharge head applications.

If a throttling valve is desired in the discharge line, use a valve as large as the largest pipe to minimize friction losses. Never install a throttling valve in a suction line.

With high discharge heads, it is recommended that a throttling valve and a system check valve be installed in the discharge line to protect the pump from excessive shock pressure and reverse rotation when it is stopped.

Bypass Lines

If it is necessary to permit the escape of air to atmosphere during initial priming or in the repriming cycle, install a bypass line between the pump and the discharge check valve. The bypass line should be sized so that it does not affect pump discharge capacity.

Either a Gorman-Rupp automatic air release valve - which will automatically open to allow the pump to prime, and automatically close when priming is accomplished - or a hand-operated shutoff valve should be installed in the bypass line.

NOTE

The bypass line may clog frequently, particularly if the valve remains closed. If this condition occurs, either use a larger bypass line or leave the shutoff valve open during the pumping operation.

Do not terminate the discharge line at a level lower than that of the liquid being pumped unless a siphon breaker is used in the line. Otherwise, a siphoning action could result, causing damage to the pump.

ALIGNMENT

The alignment of the pump and its power source is critical for trouble-free mechanical operation. In either a flexible coupling or V-belt driven system, the driver and pump must be mounted so that their shafts are aligned with and parallel to each other. It is imperative that alignment be checked after the pump and piping are installed, and before operation.

NOTE

Check $\mbox{\bf Rotation}\,,$ Section C, before final alignment of the pump.

When mounted at the Gorman-Rupp factory, driver and pump are aligned before shipment. Misalignment will occur in transit and handling. Pumps **must** be checked and realigned before operation. Before checking alignment, tighten the foundation bolts. The pump casing feet and/or pedestal feet, and the driver mounting bolts should also be tightly secured.

Section B.

CAUTION

Adjusting the alignment in one direction may alter the alignment in another direction. Check each procedure after altering alignment.

Coupled Drives

When using couplings, the axis of the power source must be aligned to the axis of the pump shaft in both the horizontal and vertical planes. Most couplings require a specific gap or clearance between the driving and the driven shafts. Refer to the coupling manufacturer's service literature.

Align spider insert type couplings by using calipers to measure the dimensions on the circumference of the outer ends of the coupling hub every 90 degrees. The coupling is in alignment when the hub ends are the same distance apart at all points (see Figure 3A).

Align non-spider type couplings by using a feeler gauge or taper gauge between the coupling halves every 90 degrees. The coupling is in alignment when the hubs are the same distance apart at all points (see Figure 3B).

Figure 3A. Aligning Spider-Type Couplings

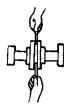

Figure 3B. Aligning Non-Spider Type Couplings

Check parallel adjustment by laying a straightedge across both coupling rims at the top, bottom, and side. When the straightedge rests evenly on both halves of the coupling, the coupling is in horizontal parallel alignment. If the coupling is misaligned, use a feeler gauge between the coupling and the straightedge to measure the amount of misalignment.

V-Belt Drives

When using V-belt drives, the power source and the pump must be parallel. Use a straightedge along the sides of the pulleys to ensure that the pulleys are properly aligned (see Figure 3C). In drive systems using two or more belts, make certain that the belts are a matched set; unmatched sets will cause accelerated belt wear.

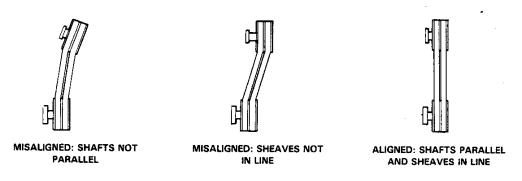

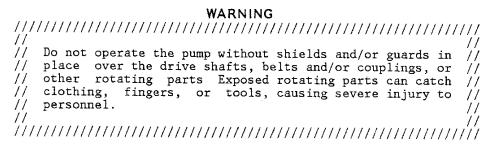

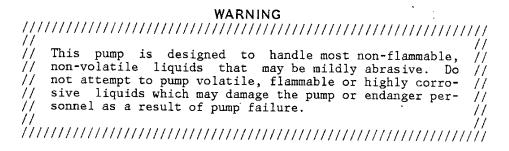

Figure 3C. Alignment of V-Belt Driven Pumps

Tighten the belts in accordance with the belt manufacturer's instructions. If the belts are too loose, they will slip; if the belts are too tight, there will be excessive power loss and possible bearing failure. Select pulleys that will match the proper speed ratio; overspeeding the pump may damage both pump and power source.

Section B.

OPERATION - SECTION C

CAUTION

Pump speed and operating condition points must be within the continuous performance range shown on the curve. See Section E, Page 1.

PRIMING

Install the pump and piping as described in INSTALLATION. Make sure that the piping connections are tight, and that the pump is securely mounted. Check that the pump is properly lubricated (see LUBRICATION in MAINTENANCE AND REPAIR).

This pump is self-priming, but the pump should never be operated unless there is liquid in the casing.

CAUTION

Never operate a self-priming pump unless there is liquid in the casing. The pump will not prime when dry. Extended operation of a dry pump will destroy the seal assembly.

Add liquid to the pump casing when:

- 1. The pump is 'sing put into service for the first time.
- 2. The pump has not been used for a considerable length of time.
- 3. The liquid in the pump casing has evaporated.

Once the pump casing has been filled, the pump will prime and reprime as necessary.

	WARNING
11/1	///////////////////////////////////////
//_	\mathcal{L}
//	After filling the pump casing, reinstall and tighten the //
//	fill plug. Do not attempt to operate the pump unless //
//	all connecting piping is securely installed. Otherwise. //
//	liquid in the pump forced out under pressure could cause //
	injury to personnel.
//	γ_{j}
////	///////////////////////////////////////

To fill the pump, remove the pump casing fill cover or fill plug at the top of the casing and add clean liquid until the pump is filled. Replace the fill cover or fill plug before operating the pump.

STARTING

Consult the operations manual furnished with the power source.

Rotation

The correct direction of pump rotation is indicated by an arrow on the pump body or accompanying decals. If the pump is operated in the wrong direction, the impeller could become loosened from the shaft and seriously damage the pump.

CAUTION

The pump must operate in the direction indicated by the arrow on the pump, or accompanying decals. Reverse rotation could loosen the impeller and seriously damage the pump.

Consult the operating manual furnished with the pump power source before attempting to start the power source.

If an electric motor is used to drive the pump, remove V-belts, couplings, or otherwise disconnect the pump from the motor before checking motor rotation. Operate the motor independently while observing the direction of the motor shaft, or cooling fan.

If rotation is incorrect on a three phase motor, have a qualified electrician interchange any two of the three phase wires to change direction. If rotation is incorrect on a single-phase motor, consult the literature supplied with the motor for specific instructions.

Page C-2

Section C.

OPERATION

Lines With a Bypass

Either a Gorman-Rupp automatic air release valve or a hand operated shutoff valve may be installed in a bypass line.

If a Gorman-Rupp automatic air release valve has been installed, close the throttling valve in the discharge line. The Gorman-Rupp valve will automatically open to allow the pump to prime, and automatically close when priming has been accomplished. After the pump has been primed, and liquid is flowing steadily from the bypass line, open the discharge throttling valve.

If a hand operated shutoff valve has been installed, close the throttling valve in the discharge line, and open the bypass shutoff valve so that the pump will not have to prime against the weight of the liquid in the discharge line. When the pump has been primed, and liquid is flowing steadily from the bypass line, close the bypass shutoff valve and open the discharge throttling valve.

Lines Without a Bypass

Open all valves in the discharge line and start the power source. Priming is indicated by a positive reading on the discharge pressure gauge or by a quieter operation. The pump may not prime immediately because the suction line must first fill with liquid. If the pump fails to prime within five minutes, stop it and check the suction line for leaks.

After the pump has been primed, partially close the discharge line throttling valve in order to fill the line slowly and guard against excessive shock pressure which could damage pipe ends, gaskets, sprinkler heads, and any other fixtures connected to the line. When the discharge line is completely filled, adjust the throttling valve to the required flow rate.

Leakage

No leakage should be visible at pump mating surfaces, or at pump connections or fittings. Keep all line connections and fittings tight to maintain maximum pump efficiency.

Liquid Temperature And Overheating

The maximum liquid temperature for this pump is 160° F. Do not apply it at a higher operating temperature.

Overheating can occur if operated with the valves in the suction or discharge lines closed. Operating against closed valves could bring the liquid to a boil, build pressure, and cause the pump to rupture or explode. If overheating

Section C. Page C-3

occurs, stop the pump and allow it to cool before servicing it. Refill the pump casing with cool liquid.

Strainer Check

If a suction strainer has been shipped with the pump or installed by the user, check the strainer regularly, and clean it as necessary. The strainer should also be checked if pump flow rate begins to drop. If a vacuum suction gauge has been installed, monitor and record the readings regularly to detect strainer blockage.

Pump Vacuum Check

Since this pump does not have a suction check valve, the discharge line must be fitted with a check valve if a pump vacuum reading is to be taken.

With the pump inoperative, install a vacuum gauge in the system, using pipe dope on the threads. Block the suction line and start the pump. At operating speed the pump should pull a vacuum of 20 inches or more of mercury. If it does not, check for air leaks in the seal, gasket, or discharge valve.

Open the suction line, and read the vacuum gauge with the pump primed and at operating speed. Shut off the pump. The vacuum gauge reading will immediately drop proportionate to static suction lift, and should then stabilize. If the vacuum reading falls off rapidly after stabilization, an air leak exists. Before checking for the source of the leak, check the point of installation of the vacuum gauge.

STOPPING

Never halt the flow of liquid suddenly. If the liquid being pumped as stopped abruptly, damaging shock waves can be transmitted to the pump and piping system. Close all connecting valves slowly.

After stopping the pump, lock out or disconnect the power source to ensure that the pump will remain inoperative.

Page C-4

Cold Weather Preservation

In below freezing conditions, drain the pump to prevent damage from freezing. Also, clean out any solids by flushing with a hose. Operate the pump for approximately one minute; this will remove any remaining liquid that could freeze the pump rotating parts.

If the pump will be idle for more than a few hours, or if it has been pumping liquids containing a large amount of solids, drain the pump, and flush it thoroughly with clean water. To prevent large solids from clogging the drain port and preventing the pump from completely draining, insert a rod or stiff wire in the drain port, and agitate the liquid during the draining process. Clean out any remaining solids by flushing with a hose.

BEARING TEMPERATURE CHECK

Bearings normally run at higher than ambient temperatures because of heat generated by friction. Temperatures up to $160\,^{\circ}\mathrm{F}$ are considered normal for bearings, and they can operate safely to at least $180\,^{\circ}\mathrm{F}$.

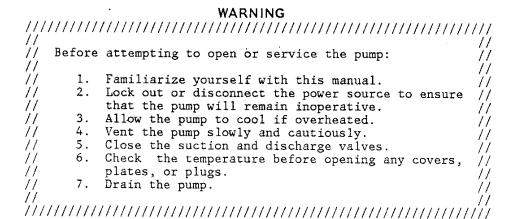

Checking bearing temperatures by hand is inaccurate. Bearing temperatures can be measured accurately by placing a contact-type thermometer against the housing. Record this temperature for future reference.

A sudden increase in bearing temperatures is a warning that the bearings are at the point of failing to operate properly. Make certain that the bearing lubricant is of the proper viscosity and at the correct level (see LUBRICATION in MAINTENANCE AND REPAIR). Bearing overheating can also be caused by shaft misalignment and/or excessive vibration.

When pumps are first started, the bearings may seem to run at temperatures above normal. Continued operation should bring the temperatures down to normal levels.

Section C. Page C-5

PUMP TROUBLESHOOTING - SECTION D

TROUBLE	POSSIBLE CAUSE	PROBABLE REMEDY
PUMP FAILS TO PRIME	Not enough liquid in cas- ing.	Add liquid to casing. See PRIM-ING.
	Suction check valve contaminated or damaged.	Clean or replace check valve.
	Air leak in suction line.	Correct leak.
	Lining of suction hose collapsed.	Replace suction hose.
	Leaking or worn seal or pump gasket.	Check pump vacuum. Replace leak- ing or worn seal or gasket.
	Suction lift or discharge head too high.	Check piping installation and install bypass line if needed. See INSTALLATION.
	Strainer clogged.	Check strainer and clean if necessary.
	Suction check valve or foot valve clogged or binding.	Clean valve.
PUMP STOPS OR FAILS TO DE- LIVER RATED FLOW OR PRES- SURE	Air leak in suction line. Suction intake not submerged at proper level or sump too small.	Correct leak. Check installation and correct submergence as needed.

Section D.

TROUBLESHOOTING

TROUBLE	POSSIBLE CAUSE	PROBABLE REMEDY
PUMP STOPS OR FAILS TO DE- LIVER RATED	Lining of suction hose collapsed.	Replace suction hose.
FLOW OR PRES- SURE(cont.)	Impeller or other wearing parts worn or damaged.	Replace worn or damaged parts. Check that impeller is properly centered and rotates freely.
	Impeller clogged.	Free impeller of debris.
	Pump speed too slow.	Check driver output; check belts or couplings for slippage.
	Discharge head too high.	Install bypass line.
	Suction lift too high.	Measure lift w/vacuum gauge. Reduce lift and/or friction losses in suction line.
	Leaking or worn seal or pump gasket.	Check pump vacuum. Replace leak- ing or worn seal or gasket.
	Strainer clogged.	Check strainer and clean if necessary.
PUMP REQUIRES TOO MUCH POW- ER	Pump speed too high.	Check driver output; check that sheaves or couplings are correct-ly sized.
	Discharge head too low.	Adjust discharge valve.
	Liquid solution too thick.	Dilute if possible.
PUMP CLOGS FREQUENTLY	Discharge flow too slow.	Open discharge valve fully to increase flow rate, and run power source at maximum governed speed.
	Suction check valve or foot valve clogged or binding.	Clean valve.

Page D-2

Section D.

TROUBLESHOOTING

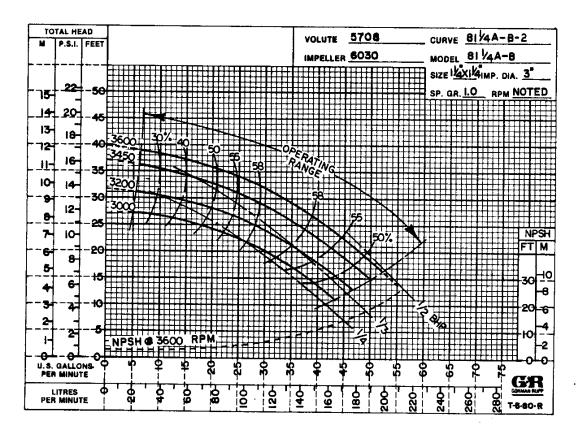

TROUBLE	POSSIBLE CAUSE	PROBABLE REMEDY		
EXCESSIVE NOISE	Cavitation in pump.	Reduce suction lift and/or friction losses in suction line. Record vacuum and pressure gauge readings and consult local representative or factory.		
	Pumping entrained air.	Locate and eliminate source of air bubble.		
	Pump or drive not securely mounted.	Secure mounting hardware.		
	Impeller clogged or dam- aged.	Clean out debris; replace damaged parts.		
BEARINGS RUN TOO HOT	Bearing temperature is high, but within limits.	Check bearing temperature regularly to monitor any increase.		
	Suction and discharge lines not properly supported.	Check piping installation for proper support.		
	Drive misaligned.	Align drive properly.

PUMP MAINTENANCE AND REPAIR - SECTION E

MAINTENANCE AND REPAIR OF THE WEARING PARTS OF THE PUMP WILL MAINTAIN PEAK OPERATING PERFORMANCE.

*STANDARD PERFORMANCE FOR PUMP MODEL 81 1/4A52-B

*Based on $70^{\circ}F$ clear water at sea level with minimum suction lift. Since pump installations are seldom identical, your performance may be different due to such factors as viscosity, specific gravity, elevation, temperature, and impeller trim.

If your pump serial number is followed by an "N", your pump is ${\sf NOT}$ a standard production model. Contact the Gorman-Rupp Company to verify performance or part numbers.

CAUTION

Pump speed and operating condition points must be within the continuous performance range shown on the curve. See Section E, Page 1.

PUMP AND SEAL DISASSEMBLY AND REASSEMBLY

This pump requires little service due to its rugged, minimum-maintenance design. However, if it becomes necessary to inspect or replace the wearing parts, follow these instructions, which are keyed to the sectional view (see Figure 1) and the accompanying parts list.

Before attempting to service the pump, lock out or disconnect the power source to ensure that it will remain inoperative while the pump is being serviced, and disconnect the suction and discharge hoses from the pump casing.

Pump Disassembly

Before attempting to service the pump, remove the casing drain plug (26) and drain the pump. Clean and reinstall the drain plug.

Remove the nuts (10) and slide the pump casing (1) off the vane plate (23) and intermediate (8). Remove the vane plate 0-ring (24) and casing gasket (22).

Remove the hardware (6 and 7) and separate the vane plate (23) from the intermediate.

To remove the impeller (2), immobilize it by placing a block of wood between the vanes. Remove the shaft key (17) and install a lathe dog on the drive end of the shaft (18) with the "V" notch over the keyway to prevent damage to the keyway. Strike the lathe dog sharply with a hammer in a counterclockwise direction (as viewed from the drive end). When the impeller breaks loose, remove the lathe dog and wood block, and unscrew the impeller from the shaft.

Remove the impeller adjusting shims (29) and spring centering washer (50). Tie and tag the shims or measure and record their thickness for ease of reassembly.

Seal Removal And Disassembly

(Figures 1 and 2)

Remove the seal spring. Apply oil to the shaft and work it up under the bellows. Slide the rotating portion of the seal off the shaft.

Use a stiff wire with a hooked end to remove the stationary element and seat.

An alternate method of removing the stationary portion of the seal is to remove the hardware (19, 20 and 21) and separate the intermediate (8) from the bearing housing (12). Position the intermediate on a flat surface with the impeller side down and use a dowel to press the stationary seat and element from the intermediate.

Shaft And Bearing Removal And Disassembly

When the pump is properly operated and maintained, the bearing housing should not require disassembly. Disassemble the shaft and bearings **only** when there is evidence of wear or damage.

CAUTION

Shaft and bearing disassembly in the field is not recommended. These operations should be performed only in a properly-equipped shop by qualified personnel.

With the intermediate and seal assembly removed, slide the slinger ring (13) off the shaft. Remove the bearing retaining ring (15) and bearing adjusting shim set (16). Tie and tag the shims or measure and record their thickness for ease of reassembly.

Use a block of wood or a soft-faced mallet to tap the shaft and assembled bearings (14) from the bearing housing (12). Use a bearing puller to remove the bearings from the shaft.

Shaft and Bearing Reassembly And Installation

Clean the bearing housing, shaft and all component parts (except the bearings) with a soft cloth soaked in cleaning solvent. Inspect the parts for wear or damage and replace as necessary.

WARNING						
1111	//////	///////////////////////////////////////	[]]]]]]]]]]]]]]]]]]	17		
//				17		
//	Most	cleaning	solvents are toxic and flammable. Use	ή		
//	them	only in a	well-ventilated area free from excessive	17		
//	heat,	sparks,	and flame. Read and follow all prec-	1		
//	aution	ns printed	on solvent containers.	Ú		
//			. '/	1		
////	'/////	///////////////////////////////////////	///////////////////////////////////////	7		

Inspect the shaft for distortion, nicks or scratches or thread damage on the impeller end. Dress small nicks and burrs with a fine file or emery cloth. Replace the shaft if defective.

Clean the bearings thoroughly in **fresh** cleaning solvent. Dry the bearings with filtered compressed air and coat with light oil.

Rotate the bearings by hand to check for roughness or binding. If rotation is rough, replace the bearings.

CAUTION

These bearings are permanently sealed and require no additional lubrication except a coating of light oil on external surfaces to ease reassembly. These external surfaces must be kept free of all dirt and foreign material. Failure to do so could damage the bearings or their mating surfaces.

The bearing tolerances provide a tight press fit onto the shaft and a snug slip fit into the bearing housing. Replace the shaft or bearing housing if the proper bearing fit is not achieved.

Inspect the bearing housing for cracks, especially around the mounting flange and at the foot. Remove nicks and burrs from the bearing seating surfaces with extra fine emery cloth or a fine honing stone.

Use an arbor (or hydraulic) press to install the bearings on the shaft until they seat squarely against the shaft shoulders.

CAUTION

When installing the bearings onto the shaft, NEVER press or hit against the outer race, balls, or ball cage. Press ONLY on the inner race.

Slide the shaft and assembled bearings into the bearing housing until the inboard bearing bottoms against the bore shoulder.

CAUTION

When installing the shaft and bearings into the bearing bore, push against the outer race. NEVER hit the balls or ball cage.

Install the same thickness of bearing shims (16) as previously removed, and install the bearing retaining ring (15). Shaft end play should be between .002 and .010 inch. Add or subtract shims (16) to obtain the correct end play.

Install the slinger ring (13) and shaft key (17) on the shaft.

Seal Reassembly And Installation

(Figures 1 and 2)

Clean the seal cavity and shaft with a cloth soaked in fresh cleaning solvent.

The seal is not normally reused because wear patterns on the finished faces cannot be realigned during reassembly. This could result in premature failure. If necessary to reuse an old seal in an emergency, carefully wash all metallic parts in fresh cleaning solvent and allow to dry thoroughly.

Handle the seal parts with extreme care to prevent damage. Be careful not to contaminate precision finished faces; even fingerprints on the faces can shorten seal life. If necessary, clean the faces with a non-oil based solvent and a clean lint free tissue. Wipe lightly in a concentric pattern to avoid scratching the faces.

Inspect the seal components for wear, scoring, grooves, and other damage that might cause leakage. If any components are worn, replace the complete seal; never mix old and new seal parts.

If a replace ent seal is being used, remove it from the container and inspect the precision finished faces to ensure that they are free of any foreign matter.

To ease installation of the seal, lubricate the bellows and stationary seat with water or a very **small** amount of oil, and apply a drop of light lubricating oil on the finished faces. Assemble the seal as follows, (see Figure 2).

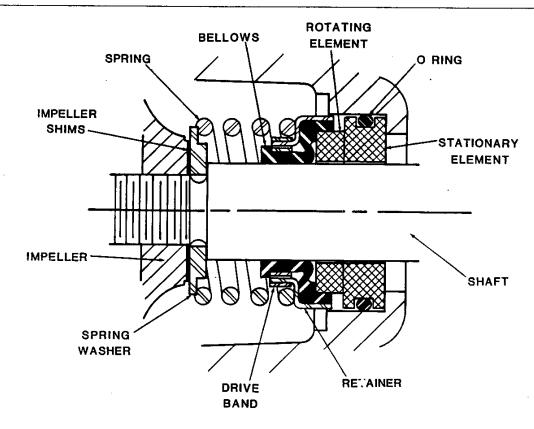

Figure 2. 25284-911 Seal Assembly

CAUTION

This seal is not designed for operation at temperatures above $160\,^{\circ}$ F. Do not use at higher operating temperatures.

Subassemble the stationary element in the stationary seat and press this subassembly into the intermediate until squarely seated against the bore shoulder.

If removed, position the intermediate (8) over the shaft and secure it to the bearing housing with the hardware (19, 20 and 21). Be careful not to damage the stationary seat when positioning the intermediate.

NOTE

It is recommended that a tapered sleeve be installed over threads of the impeller shaft to ease installation of the rotating seal elements.

Lubricate the shaft with a **small** amount of light oil and slide the rotating sub-assembly (consisting of the rotating element, bellows and retainer) onto the shaft until the seal faces contact.

Install the seal spring and spring centering washer (30).

Pump Reassembly

Inspect the impeller, and replace it if cracked or badly worn.

A clearance of .008 to .015 inch between the impeller and the vane plate is necessary for maximum pump efficiency. To achieve this clearance, install the impeller with no adjusting shims. Use a depth micrometer to measure the height of the impeller vanes from the intermediate, and the depth of the impeller cavity in the vane plate. Subtract one measurement from the other to obtain the distance between the impeller and the vane plate. Subtract approximately .012 inch from this figure to obtain the thickness of adjusting shims required.

NOTE

An alternate method of adjusting this clearance is to secure the vane plate to the intermediate and rotate the impeller shaft by hand. If the impeller binds slightly against the vane plate, remove the impeller, and remove approximately .012 inch of impeller shims. Reassemble the pump. The clearance between the impeller and the vane plate should now be correct.

If the shaft rotates freely when turned by hand, remove the impeller and add shims one at a time until the impeller binds slightly against the vane plate. When this occurs, remove approximately .012 inch of shims as indicated above.

After the proper clearance is achieved, apply '3M No. EC-847' sealant or equivalent on the contacting surfaces of the vane plate, and secure it to the intermediate with the hardware (6 and 7).

Install a new vane plate 0-ring (24) and pump casing gasket (22) and secure the pump casing to the intermediate with the nuts (10).

Install the suction and discharge hoses. Fill the pump casing with clean liquid and reinstall the fill plug.

Refer to OPERATION, Section C, before putting the pump back into service.

LUBRICATION

Seal Assembly

The seal is is lubricated by the medium being pumped, and no additional lubrication is required.

MAINTENANCE AND REPAIR

Bearings

The bearings are sealed and permanently lubricated and require no additional lubrication.

Power Source

Consult the literature supplied with the power source, or contact your local power source representative.
